

## 2. Fase de creación del Dataset insumo

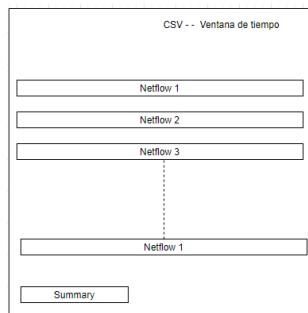

En esta fase se deberán realizar las siguientes **actividades**:

1. Se debe implementar una serie de algoritmos que permitan automatizar el proceso de traslado de pcaps a csv's
2. Se debe implementar un algoritmo que permita generar un Dataset basado en Netflows
3. Se debe implementar un algoritmo que permite generar un Dataset basado en ventanas de tiempo
4. Realizar una comparación entre ambos Datasets y escoger el mejor entre ellos

En esta fase, nuestros **entregables** son:

1. Conjunto de algoritmos que permitan la automatización del proceso de traslado de pcaps a csv's
2. Algoritmo generador de Dataset basado en Netflows
3. Algoritmo generador de Dataset basado en ventanas de tiempo
4. Comparación entre ambos Datasets
5. Dataset en formato CSV

### Entregables

Conjunto de algoritmos que permitan la automatización de traslado de pcaps a csv's

1. El siguiente algoritmo permite convertir los archivos .pcaps en un conjunto de archivos nfpcaps (ventanas de tiempo)

```
In [ ]: import os

def generationOfNfpcapsAuto(start,end, locationOfPcaps, locationsToSaveNfpcaps, netflowsLocation):

    for x in range(start, end):
        # Generation of dir that contains the nfpcaps generated with the name of the pcap
        os.chdir(netflowsLocation)
        os.system("mkdir " + str(x) + "-nfpcaps")

        # Generation nfpcap
        cmd = "nfcapd -r " + locationOfPcaps + str(x) + ".pcap -l " + locationsToSaveNfpcaps + str(x) + "-"
        print(cmd)
        os.system(cmd)

def main():
    start = 64
    end = 81
    netflowsLocation = "/home/julioce/Documentos/PDG/PDG-2/Netflows/Malignos/"
    locationOfPcaps = "/home/julioce/Documentos/PDG/PDG-2/PCAPS/Pcaps\ Malignos/"
    locationsToSaveNfpcaps = "/home/julioce/Documentos/PDG/PDG-2/Netflows/Malignos/"
    generationOfNfpcapsAuto(start,end,locationOfPcaps,locationsToSaveNfpcaps, netflowsLocation)

#main()
```

2. El siguiente algoritmo permite renombrar los nfpcaps generados en el paso anterior

```
In [ ]: import os
from os import walk

def renameFilesInDir(directory, start, end):
```

```

        for z in range(start, end):
            print("Vamos aqui:" + str(z))
            f = []
            for (dirpath, dirnames, filenames) in walk(mypath + str(z) + "-nfpcaps/"):
                f.extend(filenames)
                break

            y = 0
            for x in f:
                os.rename("/home/julioce/Documentos/PDG/PDG-2/Netflows/Malignos/" + str(z) + "-nfpcaps/" + x,
                          "/home/julioce/Documentos/PDG/PDG-2/Netflows/Malignos/" + str(z) + "-nfpcaps/nfcap")
                y = y+1

    def main():
        start = 1
        end = 81
        mypath = "/home/julioce/Documentos/PDG/PDG-2/Netflows/Malignos/"
        renameFilesAlg(mypath,start,end)

#main()

```

### 3. El siguiente algoritmo permite trasladar los nfpcaps renombrados con el algoritmo anterior a csvs

```

In [ ]: import os
from os import walk

def generationOfcsvAuto(start,end, locationOfNfpcaps, locationToSave, myPath):

    for x in range(start, end):

        os.chdir(locationToSave)
        os.system("mkdir " + str(x) + "-csves")

        numberOffiles = calculateNumberOfFiles(x, myPath)

        for y in range (0,numberOffiles):
            # Generation of csv
            cmd = "ndump -r " + locationOfNfpcaps + str(x) + "-nfpcaps/nfcapd." + str(y) + " -o csv > " +
            print(cmd)
            os.system(cmd)

def calculateNumberOfFiles(numberOfCarpet, myPath):
    f = []
    for (dirpath, dirnames, filenames) in walk(myPath + str(numberOfCarpet) + "-nfpcaps/"):
        f.extend(filenames)
        break
    return len(f)

def main():
    start = 26
    end = 81
    myPath = "/home/julioce/Documentos/PDG/PDG-2/Netflows/Malignos/"
    locationOfNfpcaps = "/home/julioce/Documentos/PDG/PDG-2/Netflows/Malignos/"
    locationToSave = "/home/julioce/Documentos/PDG/PDG-2/Datasets/Malignos/"
    generationOfcsvAuto(start,end,locationOfNfpcaps, locationToSave, myPath)

#main()

```

## Generadores

### Netflows

#### 1. El siguiente generador, permite unir todos los netflows de las ventanas de tiempo producidos por los algoritmos anteriores y pasarlo a un solo Dataset

```

In [ ]: from os import walk

def joiningAllCvs(path, start, end, dataName, nameSummary):
    flag = 0
    counter = 0
    fout = open(dataName, "a")
    summary = open(nameSummary,"a")
    for x in range (start, end):
        print("Va en : " + str(x))
        numberOffiles = calculateNumberOfFiles(x, path) - 1
        for y in range (0,numberOffiles):
            f = open(path + str(x) + "-csves/" + str(y) + ".csv")
            for line in f:
                if counter == 0:
                    if "ts" in line:
                        if flag == 0:
                            line = "References," + line
                            fout.write(line)
                            flag = 1
                elif "Summary" in line:
                    counter = 2
                else:
                    line = str(x) + "-csves/" + str(y) + ".csv," + line
                    fout.write(line)
            elif counter == 1 :

```

```

        line = str(x) + "-csves/" + str(y) + ".csv," + line
        summary.write(line)
        counter = counter -1

    else :
        counter = counter-1
    f.close() # not really needed
fout.close()
summary.close()

def calculateNumberOfFiles(numberOfCarpet, myPath):
    f = []
    for (dirpath, dirnames, filenames) in walk(myPath + str(numberOfCarpet) + "-csves/"):
        f.extend(filenames)
        break
    return len(f)
